Color

We use content color tokens to ensure text remains readable across all themes. These tokens are shown below in both light mode (left) and dark mode (right).

By applying the correct color tokens, the system can automatically adjust text color based on the active [theme](#). This means designers and developers don't need to manually switch colors for light or dark mode.

Standard text color tokens

On light backgrounds in light mode, and dark backgrounds in dark mode, we apply the standard `text-primary` and `text-secondary` color tokens.

#595e6a

Text Secondary

#f1f4f7

Text color tokens on dark surfaces

When text appears on dark surfaces (in light mode), or light backgrounds in dark mode, we use the `text-inverse` color token to maintain contrast.

Links

For [links](#) we utilize the same states as the [buttons](#), to give users clear visual feedback that their interaction is being registered. Each state has it's own color.
